

Brief summary of the incident

The network protocol analyzer logs indicates that port 53 is unreachable when attempting to access the website using UDP protocol. Port 53 is normally used for interaction with DNS servers. This may indicate a problem with the DNS servers or firewall configuration.

Full summary

The incident occurred in the midday, when general users couldn't access the website www.yummyrecipesforme.com, and saw the error "destination port unreachable" after waiting for the page to load. The network security team responded and began running tests with the network protocol analyzer tool tcpdump. To load the webpage, our browser have sent a query to a DNS server via the UDP protocol to retrieve the IP address for the website's domain name. The resulting logs revealed that port 53, which is used for interaction with DNS servers, is not reachable. We are continuing to investigate the root cause of the issue to determine how we can restore access to the website and the port 53 itself. Our next steps include checking the DNS and firewall configuration to see if port 53 is blocked and contacting the system administrator for the web server to have them check the system for signs of an attack. The HR team believes it is possible that a certain new hire may want to keep us from performing DNS check. The network security team suspects this person might have launched an attack to crash DNS servers.
